

King's South TX Native Grass Mix

Best time to plant:
Mid-February to Early June
Planting Rate:
5-10 lbs per acre

Planting Depth:

1/4 inch. Rake and press

Sunlight: 6 to 8 hrs per day

Soil Type: Prefers clay to clay loam soils

Regions: South Texas

Irrigation:

- Day 1 to 10—every day
- Day 10 to 2nd month water 2x a week
- 2 to 4 months— water 2x a month

Height: 1 – 5 feet tall

Use:

Wildlife

Erosion Control

Highway Right of Ways

rigilwdy Right of Wdys

King's South Texas Native Mix is made up of varieties that do particularly well in South Texas. The mix of Natives can be used for a variety of uses and is recommended for use in upland wildlife, highway right-of-ways, energy exploration, erosion control, and range plantings in South Texas. The mix can grow anywhere from 3 to 5 feet tall with some grasses that only grow 1-2 feet filling in closer to the ground to ensure a good stand. It is important to plant several species to take advantage of the diverse characteristics of each grass.

King's South Texas Native Mix is a pre-mixed blend that can be applied to various areas around South Texas. If a specific mix is required a custom mix can be prepared for your particular region.

Planting: Planting methods and soil bed preparation are critical to having successful results when establishing all grasses.

Apply seed with a broadcaster type seeder, or preferably a native

grass seed drill. Existing weeds should be controlled mechanically or with herbicides. The seed-bed soil should be freshly disturbed just prior to planting. Roll or drag lightly to cover seed to a depth of no more than 1/4 inch. Rolling is generally preferred to dragging.

Newly planted perennial grasses should not be grazed prior to the young plants reaching a height of 18" to 24". At this stage grazing should be kept to a minimum and only in short duration with a low number of animals. In many instances emergence is not uniform and you should exercise caution not to graze a newly planted pasture based only on the largest plants. There is always the possibility that late emerging plants will be grazed before they can establish.

Getting the Best Success from Your Seed

The key traits of a person who has a "green thumb" are patience and attention.

Patience is needed because all of your seed will not germinate at once. Attention is needed to ensure that you plant your seed at the right depth and at the optimal time.

Seeds have limited energy, if planted too deep they use up their energy before reaching the surface and die. However, if you plant to shallow the seed could dry out, blow away, or be eaten by birds.

Focus on the things you can control:

- 1. Planting Depth—Pay attention to the recommended planting depth for each species. For many of the species we sell, a quarter-inch deep is all that is needed.
- 2. Timing is Everything!—It's very important to know when to plant. If you get it in the ground during the optimal windows of time, the plants know when to grow. They need adequate moisture and ideal soil temperature. Moisture is something we can control; temperature we cannot. Plant during the recommended planting time and, if possible, irrigate the area for ideal moisture.
- 3. Know Your Region—Plant the right seed for your region. If you don't know what your region is, ask us!
- 4. Prepare the Seedbed—Preparing the seedbed before you plant is very important. Try to remove all the other vegetation prior to planting by tilling or spraying an herbicide. The soil should be soft but not too loose. A good indicator is if your shoes leave a print in the soil, but don't sink in.
- 5. Know Your Seed Type—Getting your seed spread out in an even matter will help you ensure a successful planting. Seed spreaders can help, but only if you get the tool that works best with your type of seed. For small areas, like a garden, hand spreading will work. It is important to match your seed to your planter or your planter to your seed!
